Polynomial SVM Hyperparams

Created	October 15, 2026 11:50 PM
Class	DEPI
Made By	 Kevin Harvey

- `C` (Regularization Parameter): Controls the penalty of the model, a small `C` allows more misclassifications, while a large `C` penalizes them harder therefore allowing less missclassification but may increase the risk of overfitting
- `r`: Controls the independent constant term in the polynomial kernel. It influences how much lower-order terms contribute to the decision boundary.
- `gamma`: Controls the influence of individual training samples on the decision boundary. A higher gamma gives each sample more influence, while a lower gamma produces a lower influence
- `d` (degree): Specifies the degree of the polynomial kernel,
  a higher degree allows more complex decision boundaries but may increase the risk of overfitting
- `kernel`: Specifies the function used by the SVM to transform data and determine decision boundaries, in this case it's `poly` ,but it's not limited to that only. because there's `linear` , `rbf` , `sigmoid`
